

Kiro CLI

Overview

In this section you will use the Kiro Command Line Interface (CLI) to extend and fix unit tests in your project through the terminal.

Using Kiro CLI

[Kiro CLI](#) allows you to use Kiro agents in your favorite terminal to build powerful features, analyze errors, suggests fixes, automate workflows in seconds.

Key features include:

- Prompt to code to deployment in your terminal.
- Build features in complex codebases.
- Automate workflows in seconds.
- Analyze errors, and trace bugs with precision.
- Use Kiro CLI to format code, run tests, manage logs, and more - all through automated shell commands.
- Use [custom agents](#) in a highly interactive terminal experience.
- Use your [knowledge base](#), [steering files](#), and [MCP tools](#), to deliver production-grade code, documentation, and tests that match your requirements.
- [Build task-specific custom agents](#) optimized for your best practices through pre-defined tool permissions, context, and prompts.

Note

As it is available on your terminal, it can be used in any terminal window in any IDE, even outside the Kiro IDE!

Install Kiro CLI

1. Go to [Kiro CLI](#) and run the command to install Kiro CLI onto your system.

Authenticating to Kiro CLI

Before using the Kiro CLI, authenticate with your AWS Builder ID.

1. Run the following command in an IDE terminal:

```
kiro-cli login
```

2. For **Select login method**, choose **Use for Free with Builder ID**.
3. Holding the **Command** key (Mac) or **Control** key (Windows), select the URL.
Choose **Open** to open a new browser tab.
4. For **Authorization requested**, choose **Confirm and continue**.

Note

If you did not use the Builder ID to connect to the workshop, or do not have one already setup, follow the prompts to setup a new Builder ID.

5. Choose **Allow access**.
6. The window will show **Request approved**. Close the tab and return back to your terminal.
7. Test you are connected using the following command:

```
kiro-cli whoami
```

Using Kiro CLI

After authenticating with `kiro-cli login`, start an interactive chat session:

```
kiro-cli chat
```

This command initiates an interactive chat session with the Kiro CLI in your terminal. You can ask questions, request code samples, troubleshoot issues, and even have Kiro CLI execute commands on your behalf.

When Kiro CLI needs to execute a command on your system, it will prompt you for permission. You have three response options:

- `y` (yes): Allow Kiro CLI to execute the command once.

- `n` (no): Deny execution of the command.
- `t` (trust): Allow Kiro CLI to execute this and similar commands without asking again during the current session.

Best practices for using Kiro CLI

See all supported commands by running `kiro-cli --help-all` .

When interacting with Kiro CLI, best practices include:

- Be specific in your prompt.
- Include relevant code snippets for context.

Use the Kiro CLI to extend unit tests

You will use the Kiro CLI to help us extend unit tests in our code.

1. Run the following command in the terminal window.

```
kiro-cli chat "Review and extend the unit tests in the test subdirectory." 
```

The agent will search the folder and propose some sample tests. Review the code, and choose `y` to accept the proposed code, and then move to the next file.

After a few iterations, choose `t` to indicate that you trust the Kiro CLI to generate the code without further prompting. the Kiro CLI will continue to iterate to generate and test the changes.

Once complete, the Kiro CLI will summarize the changes.

Use the Kiro CLI to run and fix the unit tests

1. Use the Kiro CLI to run and automatically fix the unit tests.

► Example prompts

2. Use `/quit` to exit from the chat session.

Summary

Congratulations! You have used the Kiro CLI to iterate through your project and generate unit tests. You have also used the Kiro CLI to run and fix the tests, and interacted with your project using natural language.
